# Sequential Logic Jinyang Li

# What we've learnt so far

- Combinatorial logic
  - E.g. Multiplexors (Mux), Decoders
  - Two ways of building a CL
    - Truth table  $\rightarrow$  sum of products circuits
    - ROM
- ALU
  - Compute all operations (+, OR, AND, NOR), multiplexer picks the result
  - Building a 64-bit adder
    - Ripple carry chains together 1-bit adders
    - Carry lookahead

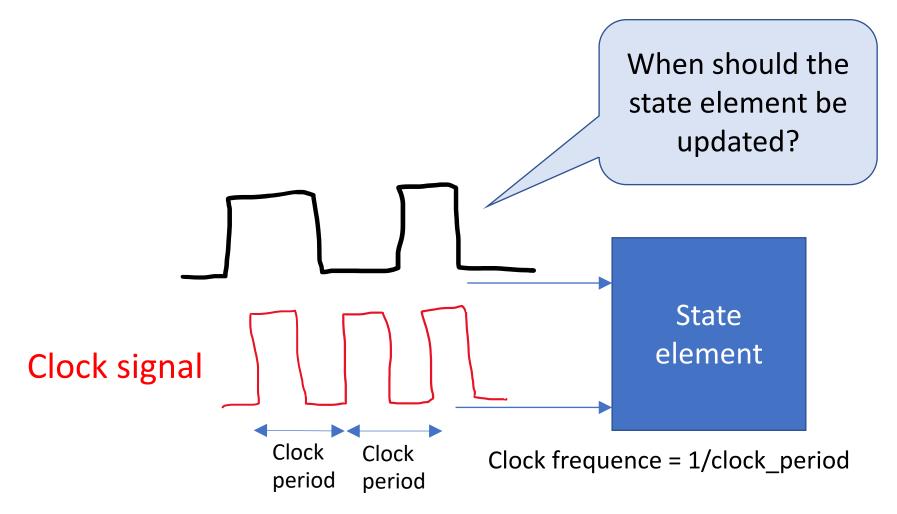

# Today's lesson plan

- Sequential circuit: Memory (state) elements
- Sequential circuit: Finite State Machine

# Two types of logic circuits

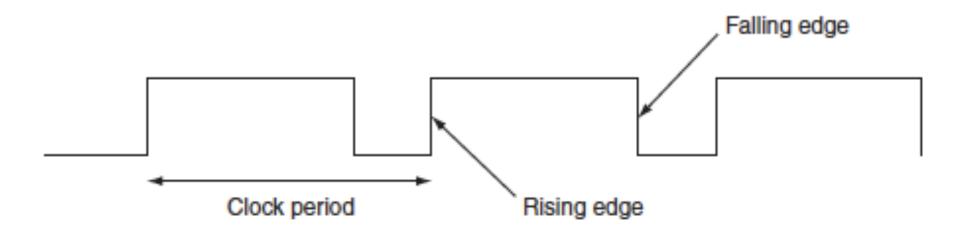

- Combinatorial circuit
  - PLA: Truth table  $\rightarrow$  sum of products PLA circuit
  - ROM (read-only memory): Addresses (inputs) → contents (outputs)
- Sequential circuit
  - output is dependent on both input and state (memory elements)

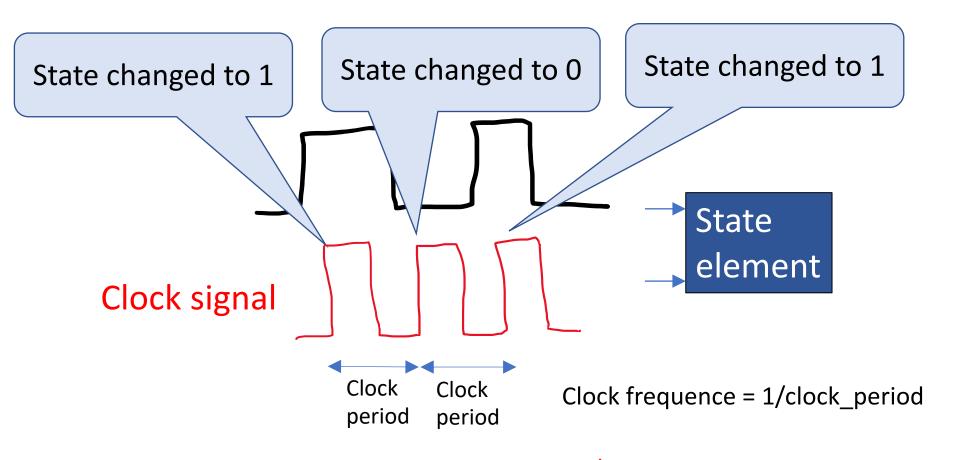

Today's lesson

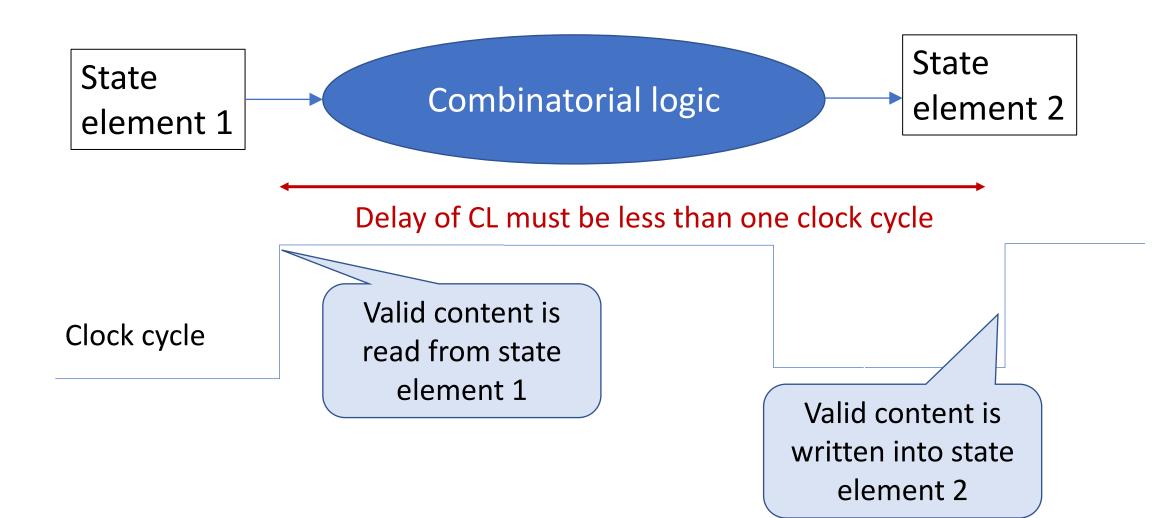

# Clocks

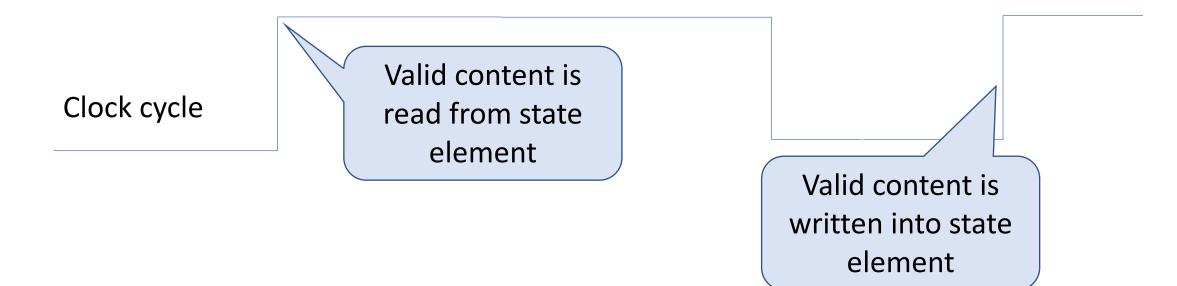

• Edge-triggered clocking: state content only changes on active clock edge

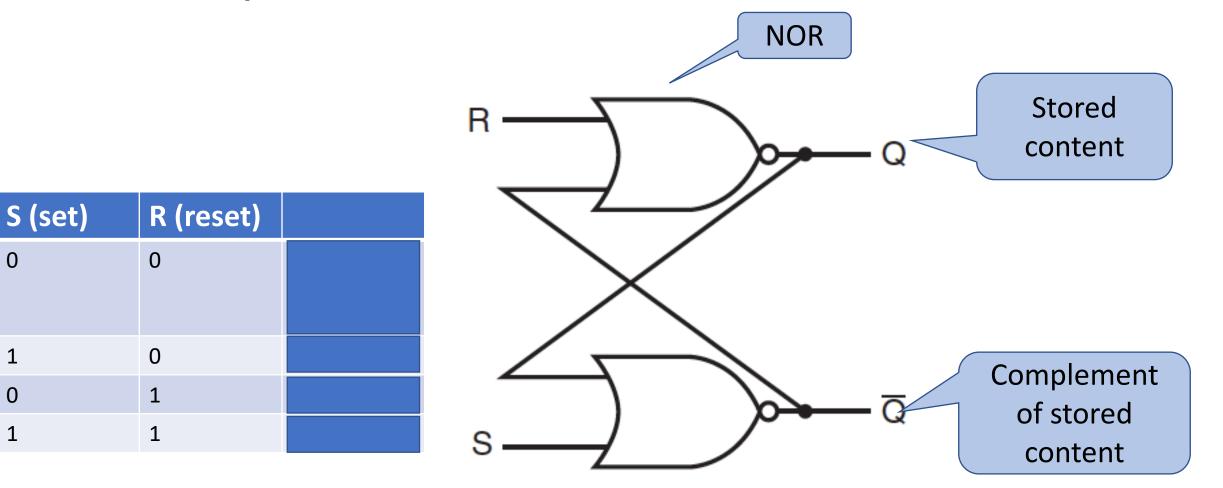

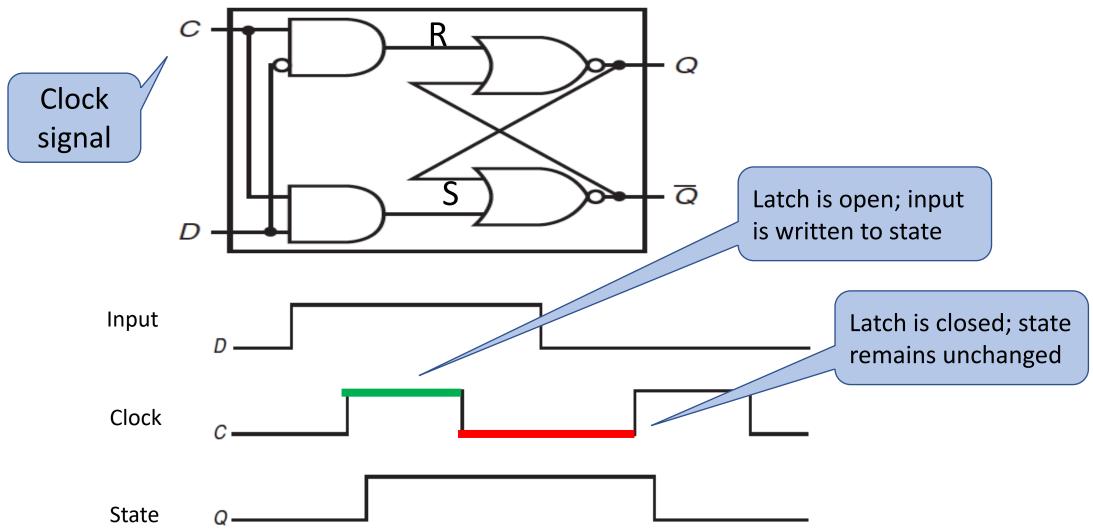

#### Memory (state) elements: unlocked S-R Latch

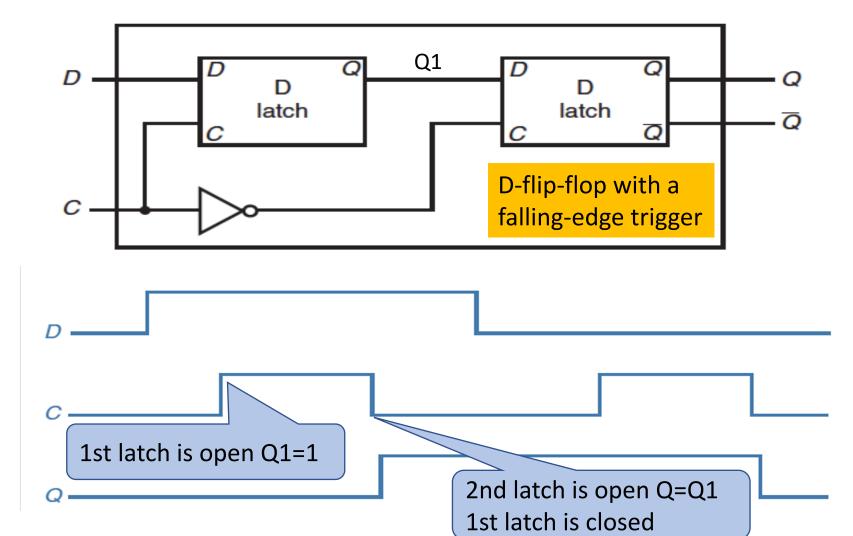

## Memory element: clocked D latch

• D latch: state is changed as long as clock is asserted

## Memory element: Flip-flop

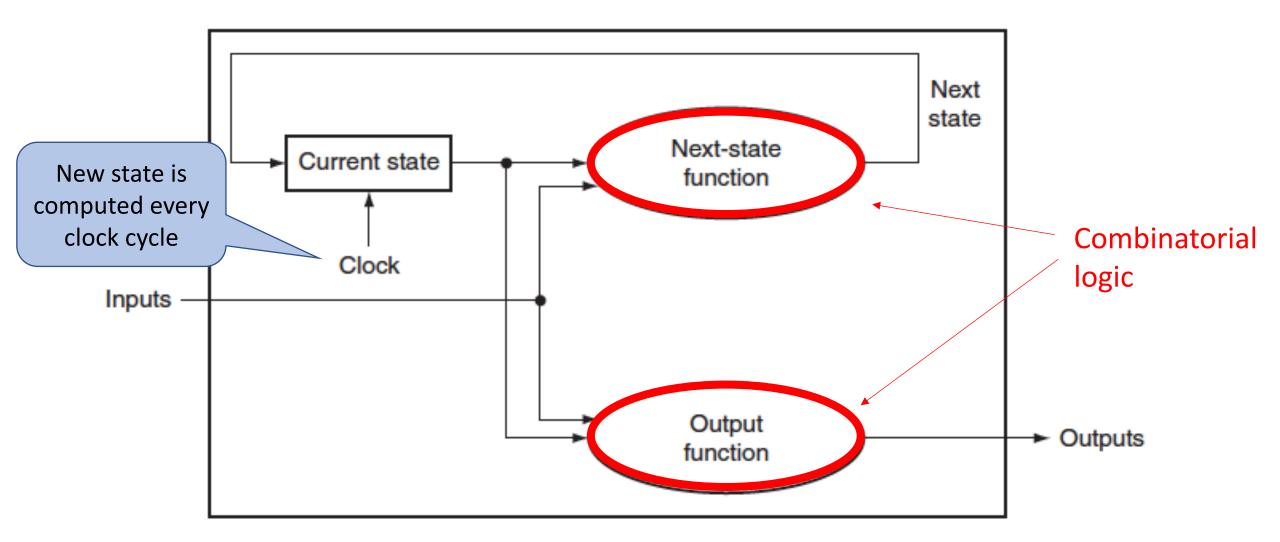

• Flip-flop: state is changed only on (rising or falling) clock edge

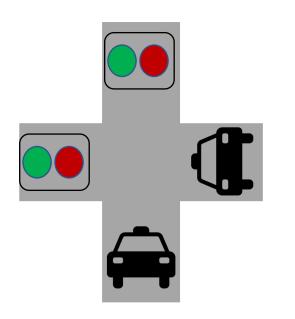

#### Finite State Machine

- Combinatorial logic  $\rightarrow$  truth table
- Sequential logic  $\rightarrow$  F(inite) S(tate) M(achine)
  - Input and current state determine next state and outputs

#### Finite State Machine

## FSM example: traffic light control

State: -

How many bits needed to represent state values?

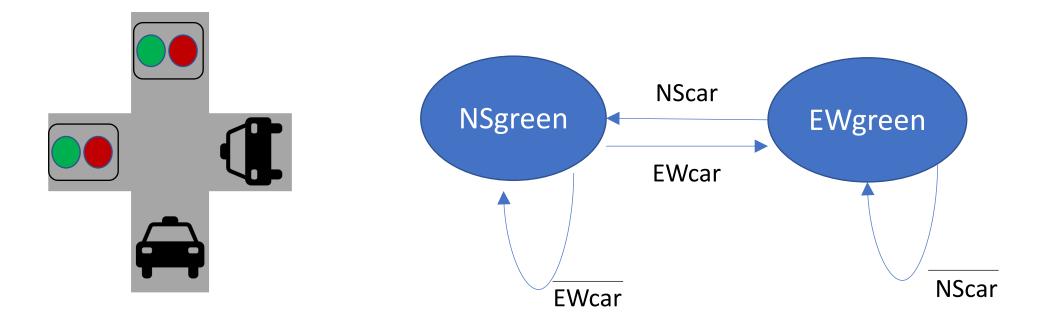

NSgreen: traffic light is green in N-S (red in E-W) EWgreen: traffic light is green in E-W (red in N-S)

Inputs:

NScar: car detected in N-S EWcar: car detected in E-W

Outputs: NSlite: 1 if state=NSgreen EWlite: 1 if state=EWgreen

#### FSM example: traffic light control

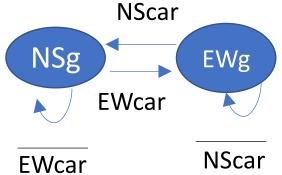

Clock speed? Clock cycles once every 30 seconds

# FSM example: traffic light

• FSM is determined by NextState function and Output function

	Inputs				
	NScar	EWcar	Next state		
NSgreen	0	0	NSgreen		
NSgreen	0	1	EWgreen		
NSgreen	1	0	NSgreen		
NSgreen	1	1	EWgreen		
EWgreen	0	0	EWgreen		
EWgreen	0	1	EWgreen		
EWgreen	1	0	NSgreen		
EWgreen	1	1	NSgreen		

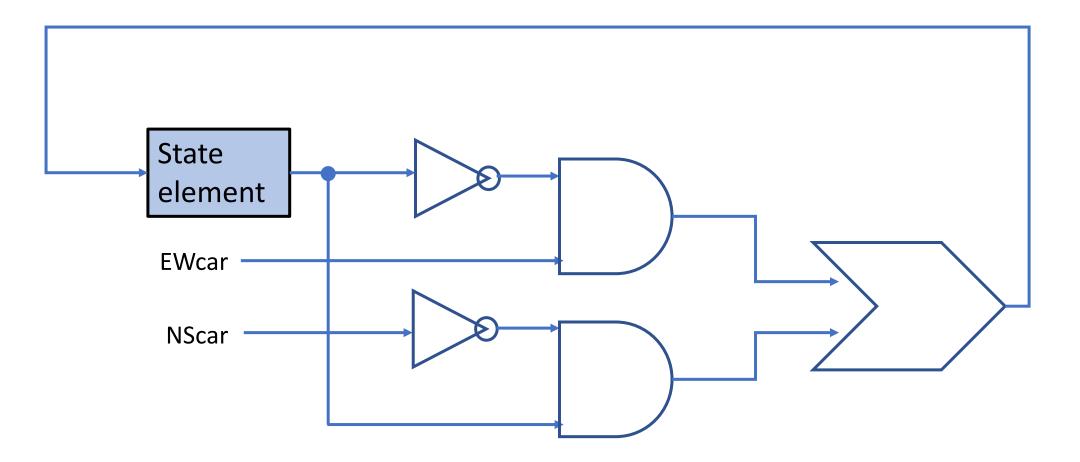

# FSM example: traffic light

• FSM is determined by NextState function and Output function

	Inputs				
Current State	NScar	EWcar	Next state		
0 (Nsgreen)	0	0	0 (Nsgreen)	Next	
0 (Nsgreen)	0	1	1 (Ewgreen)		
0 (Nsgreen)	1	0	0 (Nsgreen)	+	
0 (Nsgreen)	1	1	1 (Ewgreen)	- <b>-</b>	
1 (Ewgreen)	0	0	1 (Ewgreen)		
1 (Ewgreen)	0	1	1 (Ewgreen)		
1 (Ewgreen)	1	0	0 (Nsgreen)		
1 (Ewgreen)	1	1	0 (Nsgreen)		

#### FSM traffic light: next state function

 $Next = \overline{Curr} \cdot EWcar + Curr \cdot \overline{NScar}$ 

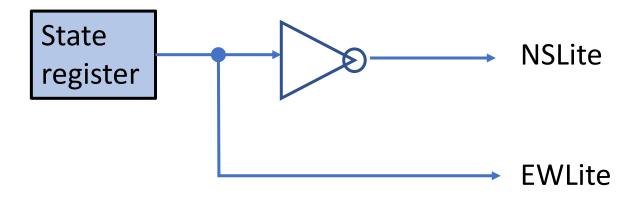

# FSM traffic light: output function

	Outputs		
	NSlite	EWlite	
0 NSgreen	1	0	
1 EWgreen	0	1	

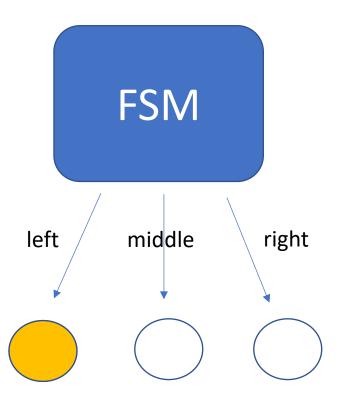

NSLite =  $\overline{Curr}$ EWLite = Curr

#### FSM traffic light: output function

# Another FSM example: Electronic eye

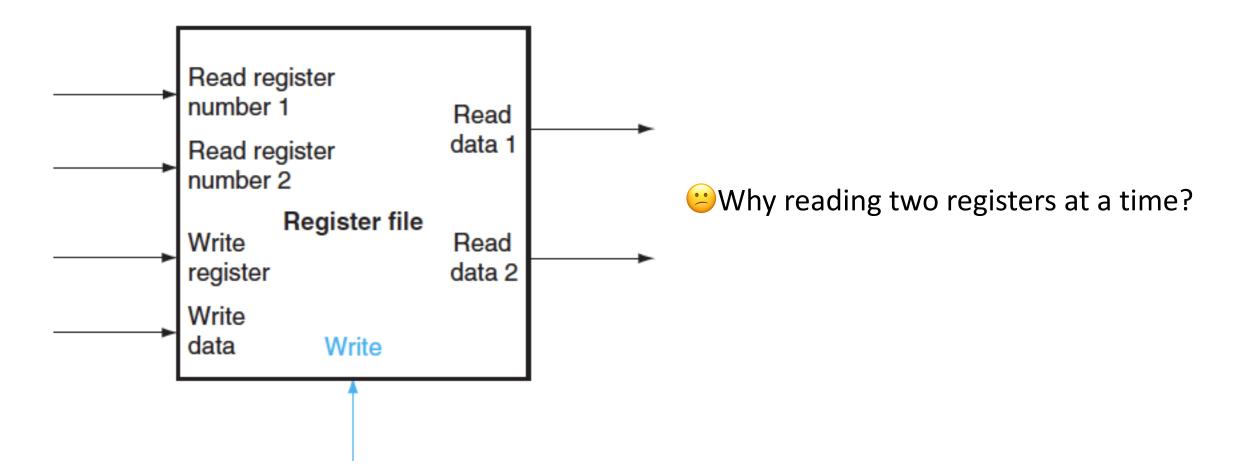

State transition diagram?

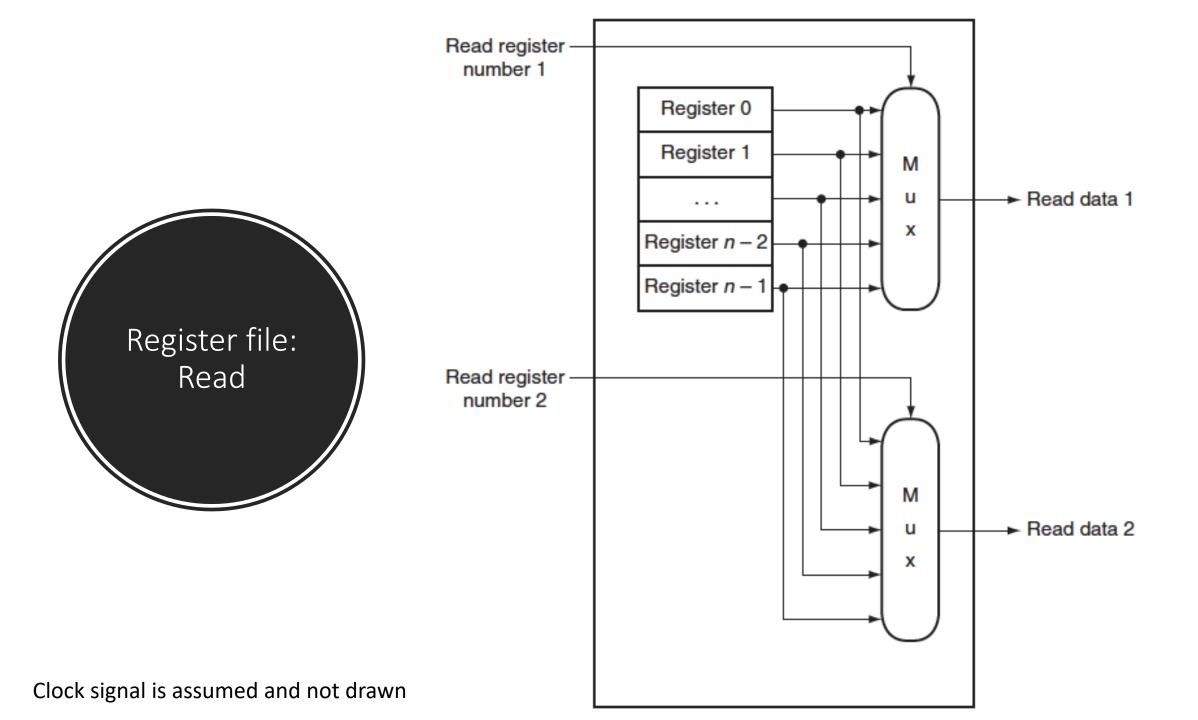

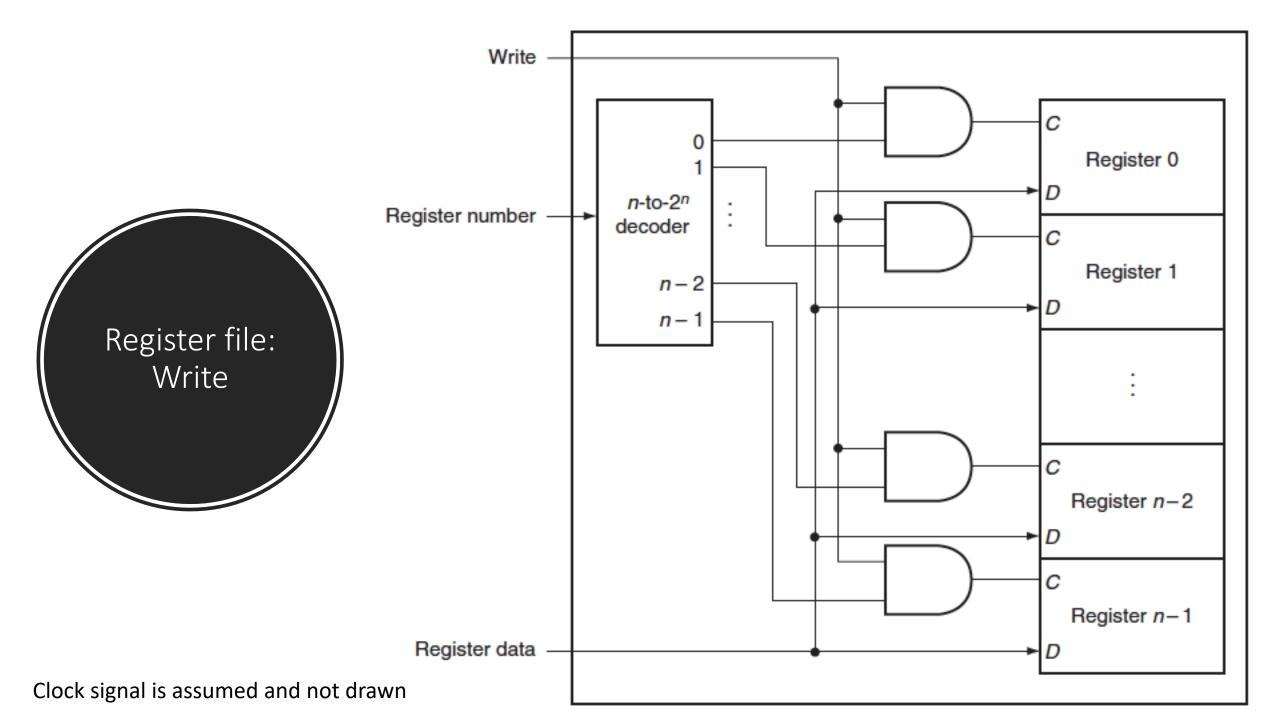

Lights are lit from left to right, then right to left and so on

## Memory element: Register file

• Register file: a set of registers that can be read and written

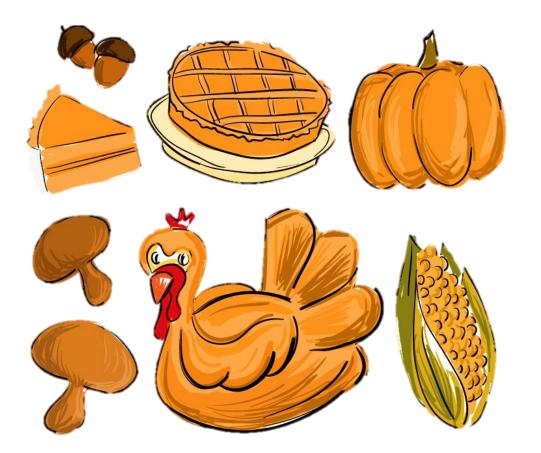

# Register file

- What if the same register is read and written in the same clock cycle?
  - Return register value written in an earlier cycle
  - Write of new value occurs on the clock edge (at the end of the current cycle)
- Some register file can read value currently being written
  - Requires additional logic in the register file

# Summary

- Memory (state) elements
  - Requires a clock signal to know when to update state value
  - Unclocked S-R latch  $\rightarrow$  Clocked D latch  $\rightarrow$  Flip-flop
- Sequential logic
  - Finite state machine
  - Decompose into two CL functions
    - Next state function: compute next state value based on current state value and inputs
    - Output function: compute output based on current state value and inputs

# Happy Thanksgiving!

Stay safe!
